

Lab Report 1:

Strategy: We pinged all devices in adjacent subnets from each device in a certain subnet (e.g., pinging R2 F1/0 and R1 eth1 from PC3, PC4, PC5). In some cases, we had to edit the `/etc/networking/interfaces` file and ensure the default gateway to reach neighboring subnets was correct, then restart the networking service using the command: `sudo /etc/init.d/networking restart`. We also ran wireshark on connections that were part of the route we took in order to verify that ping requests were getting successful replies.

- A. All pings were successful. The pings within this subnet had faster RTT than pings outside the subnet. Occasionally, an ARP was sent to verify which devices had a certain IP address. The below wireshark capture came from the R3-SW1 connection.

```
R3#ping 10.1.3.1

Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 10.1.3.1, timeout is 2 seconds:
!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 8/10/12 ms
R3#ping 10.1.3.2

Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 10.1.3.2, timeout is 2 seconds:
!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 16/22/32 ms
R3#ping 10.1.2.4

Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 10.1.2.4, timeout is 2 seconds:
!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 32/35/40 ms
```

- D. The ubuntu router in part(b) was not forwarding packets from its eth0 port to eth1. We checked R1->SW2 with wireshark, and found that packets were being directed using the following path: R3->R2->R1. SW2 sent ARP requests that R1 replied to, but the ping still received no response. When we ran wireshark from SW1 -> R2, no traffic was captured.

Capturing from - [R1(UbuntuDesktop) Ethernet1 to SW2 Ethernet1]

No.	Time	Source	Destination	Protocol	Length	Info

- E. Reverse-path filtering is a possible solution to this, it allows for asymmetric routing, which solves the issue for when R3 could not route to R1.

Lab Report 2:

We think that R2 is only forwarding packets from the 10.1.3.0 subnet to the 10.1.2.0 subnet in one direction. We edited the `/etc/sysctl.conf` file to enable loose filtering by setting `net.ipv4.conf.all.rp_filter=2` and enabling the default filter. After restarting the linux router, the ICMP ping from 10.1.3.3 to 10.1.2.1 successfully returned.

```
R3#ping 10.1.2.1
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 10.1.2.1, timeout is 2 seconds:
!!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 12/24/52 ms
```

Lab Report 3:

- A. PC1 sent out 1 packet.
- B. Route: **PC1->R3->SW1->R2->SW2->R4->SW2->R1->SW1->R3->PC1**
It's interesting that the probe packets took an asymmetric route back.
- C. PC1 received 3 reply packets from R3, R2, and R4
 - i. R3 -> PC1
 - ii. R2 -> SW1 -> R3 -> PC1
 - iii. R4 -> SW2 -> R1 -> SW1 -> R3 -> PC1
- D. Yes, they were successful. The path that was taken is a valid path to R4.

Lab Report 4:

```
@PC1: ~
@PC1:~$ sudo traceroute -I -n -q 1 -N 1 10.1.2.4
sudo: unable to resolve host PC1
traceroute to 10.1.2.4 (10.1.2.4), 30 hops max, 60 byte packets
 1  10.1.4.1  7.173 ms
 2  10.1.3.2  35.216 ms
 3  10.1.2.4  51.809 ms
@PC1:~$ sudo traceroute -I -n -q 1 -N 1 10.1.1.1
sudo: unable to resolve host PC1
traceroute to 10.1.1.1 (10.1.1.1), 30 hops max, 60 byte packets
 1  10.1.4.1  10.321 ms
 2  10.1.3.1  21.231 ms
 3  10.1.1.1  41.756 ms
@PC1:~$
```

These routes are not congruent because we added a new static route for R3 that directs traffic to the 10.1.1.0 subnet to take 10.1.3.1 as its next hop. Since R3 does not recognize the 10.1.2.0 subnet, it sends packets with that destination address to its default gateway - 10.1.3.1(R1).

Lab Report 5:

```
@PC2: ~
@PC2:~$ sudo traceroute -I -n -q 1 -N 1 10.1.1.4
sudo: unable to resolve host PC2
traceroute to 10.1.1.4 (10.1.1.4), 30 hops max, 60 byte packets
 1  10.1.5.1  5.294 ms
 2  10.1.3.1  24.014 ms
 3  10.1.2.4  25.253 ms
 4  10.1.1.4  49.604 ms
@PC2:~$

@PC4: ~
@PC4:~$ sudo traceroute -I -n -q 1 -N 1 10.1.5.2
sudo: unable to resolve host PC4
[sudo] password for bigdaddy:
traceroute to 10.1.5.2 (10.1.5.2), 30 hops max, 60 byte packets
 1  10.1.1.1  9.404 ms
 2  10.1.2.1  22.721 ms
 3  10.1.3.3  30.273 ms
 4  10.1.5.2  41.168 ms
@PC4:~$
```

These routes are symmetric. This is because the static routes were configured in a symmetric manner. PC2's default gateway, R3, routes traffic heading to the 10.1.1.0 subnet to R1, then R1 routes to R4. Conversely, PC4's default gateway, R4, routes traffic heading to the 1.1.5.0 subnet to R1, then R1 routes to R3.

Lab Report 6:

```
@PC2: ~
@PC2:~$ sudo traceroute -I -n -q 1 -N 1 10.1.1.3
sudo: unable to resolve host PC2
traceroute to 10.1.1.3 (10.1.1.3), 30 hops max, 60 byte packets
 1  10.1.5.1  12.694 ms
 2  10.1.3.2  39.830 ms
 3  10.1.2.4  45.243 ms
 4  10.1.1.3  54.387 ms
@PC2:~$
```

```
@PC3: ~
@PC3:~$ sudo traceroute -I -n -q 1 -N 1 10.1.5.2
sudo: unable to resolve host PC3
traceroute to 10.1.5.2 (10.1.5.2), 30 hops max, 60 byte packets
 1  10.1.1.1  12.534 ms
 2  10.1.2.1  21.258 ms
 3  10.1.3.3  42.725 ms
 4  10.1.5.2  53.425 ms
@PC3:~$
```

These routes are asymmetric. This is because we configured R3 to treat PC3 as its own subnet with its next hop being 10.1.3.2. Conversely, PC3's traceroute to PC2 is being routed from its default gateway, R3 to R1 since we have a static route that tells R3 to route packets heading to the 1.1.5.0 subnet to R1.

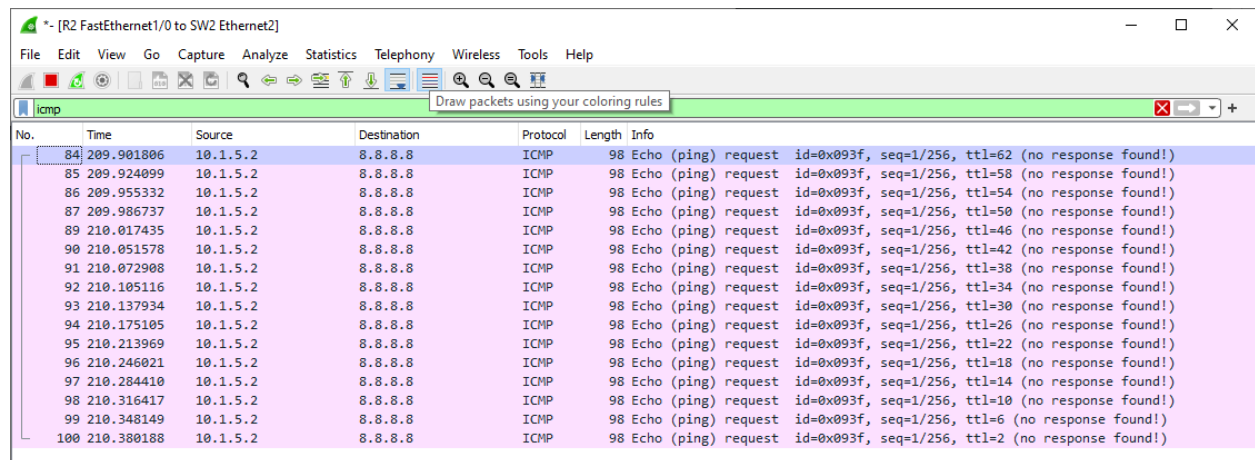

Lab Report 7:

```
@PC2: ~
@PC2:~$ sudo traceroute -I -n -q 1 -N 1 8.8.8.8
sudo: unable to resolve host PC2
traceroute to 8.8.8.8 (8.8.8.8), 30 hops max, 60 byte packets
 1  10.1.5.1  11.651 ms
 2  10.1.3.2  33.235 ms
 3  10.1.3.2  30.803 ms !H
@PC2:~$
```

```
@PC4: ~
@PC4:~$ sudo traceroute -I -n -q 1 -N 1 8.8.8.8
sudo: unable to resolve host PC4
[sudo] password for bigdaddy:
traceroute to 8.8.8.8 (8.8.8.8), 30 hops max, 60 byte packets
 1  10.1.1.1  14.178 ms
 2  10.1.2.1  21.680 ms !N
@PC4:~$
```

Both PC2's traceroute determined that the host is unreachable, while PC4 determined that the network was unreachable. In PC2's case, this is because its default gateway, R3, defaults to R2. Because R2 has no default gateway, it resolves as the host not being found. A similar thing happens with PC4, but in its case, its default gateway (R4) defaults to R1. Since R1 has no default gateway, it returns unresolved.

Lab Report 8:

No.	Time	Source	Destination	Protocol	Length	Info
84	209.901806	10.1.5.2	8.8.8.8	ICMP	98	Echo (ping) request id=0x093f, seq=1/256, ttl=62 (no response found!)

96	210.246021	10.1.5.2	8.8.8.8	ICMP	98	Echo (ping) request id=0x093f, seq=1/256, ttl=18 (no response found!)
97	210.284410	10.1.5.2	8.8.8.8	ICMP	98	Echo (ping) request id=0x093f, seq=1/256, ttl=14 (no response found!)
98	210.316417	10.1.5.2	8.8.8.8	ICMP	98	Echo (ping) request id=0x093f, seq=1/256, ttl=10 (no response found!)
99	210.348149	10.1.5.2	8.8.8.8	ICMP	98	Echo (ping) request id=0x093f, seq=1/256, ttl=6 (no response found!)
100	210.380188	10.1.5.2	8.8.8.8	ICMP	98	Echo (ping) request id=0x093f, seq=1/256, ttl=2 (no response found!)

The ping only sent out 1 packet. Wireshark captured 1 packet being sent out 17 times, albeit at different intervals. The last capture of the ICMP request (frame 100) was right before the request expired. This is observed by looking at its TTL. That is because we created a routing loop by adding a default gateway that directs traffic from R2 -> R4, and another default gateway that directs traffic from R1 -> R3. This creates a loop for our default gateways (i.e., default traffic that enters at R3 takes the path R3->R2->R4->R1->R3...).

Lab Report 9:

No.	Time	Source	Destination	Protocol	Length	Info
4	18.270660	10.1.5.2	8.8.8.8	ICMP	74	Echo (ping) request id=0x0960, seq=3/768, ttl=1 (no response found!)

14	18.697685	10.1.5.2	8.8.8.8	ICMP	74	Echo (ping) request id=0x0960, seq=10/2560, ttl=8 (no response found!)
15	18.729121	10.1.5.2	8.8.8.8	ICMP	74	Echo (ping) request id=0x0960, seq=10/2560, ttl=4 (no response found!)

There are 12 packets being captured in this example. As specified in the traceroute command the max amount of hops (max ttl) will be 10. In wireshark we can see 12 packets being recorded all with the same source ip as PC2, and same id. The packets captured by wireshark are responses from the routers with the id of the packet, the sequence and the time to live of the packet. The information we see on wireshark is used to determine the amount of hops to that router, we see that a response packet with a ttl=8 is 8 hops out, we also see that another probe packet is to be sent out simultaneously and it had a max ttl of 4. We see that the sequence number is the amount of hops we are allowed, there are 10 sequences, each packet shows in which sequence they are in. The mapping we have can be seen from the table below:

Device	Sequence	TTL	Next-Hop
PC2	0	-	R3
R3	1	-	SW1
SW1	2	-	R2
R2	3	1	SW2
SW2	4	2	R4
R4	5	3	SW3
SW3	6	4	R4
SW3	7	5	R4
R4	7	1	SW2
R4	8	6	SW2
SW2	8	2	R1
SW2	9	7	R2
R1	9	3	SW1
R2	10	8	-
SW1	10	4	-
